Getting started with \boldsymbol{R}

- Introduction
- 2 Vectors
- Matrices and arrays
- 4 List
- Data frames and tibbles
- Importing & exporting data

Handling data in \boldsymbol{R}

There are many types of objects designed to store data in \mathbf{R} .

We will focus on:

- vectors
- matrices (and arrays)
- data frames (and tibbles)
- lists

Note: if you master those, we are pretty much all set because most other objects derive from those!

Handling data in ${\bf R}$

- vectors
 - a single row of data
 - all elements have the same type (e.g. logical, integer, double, character...)
- matrices (and arrays)
 - all rows & columns have same length
 - all rows & columns have the same type
- data frames (and tibbles)
 - all rows & columns have same length
 - · each column can have its own type
- lists
 - each element can have its own length
 - each element can have its own type

Getting started with \boldsymbol{R}

- Introduction
- 2 Vectors
- Matrices and arrays
- 4 List
- Data frames and tibbles
- 6 Importing & exporting data

Vector

The vector is the simplest way to store data in **R**; it is a sequence of data elements of the same type.

Example of a vector:

```
height_girls <- c(178, 175, 159, 164, 183, 192)
height_girls
## [1] 178 175 159 164 183 192
```

Getting started with R

- Introduction
- Vectors
 - general properties
 - types & classes
 - factors
 - functions
- Matrices and arrays
 - general properties
 - functions
- List
 - general properties
 - functions
- Data frames and tibbles
 - general properties
 - challenge
 - functions
 - dplyr
 - tidyr
 - tibbles
- Importing & exporting data

They can be combined:

```
height_boys <- c(181, 189, 174, 177)
height <- c(height_boys, height_girls)
height
## [1] 181 189 174 177 178 175 159 164 183 192
```

Subsets can be made (with indexes, booleans or names):

```
height_girls[2] ## returns element 2
## [1] 175
height_girls[-3] ## remove element 3
## [1] 178 175 164 183 192
```

Subsets can be made (with indexes, booleans or names):

```
height_girls[2] ## returns element 2
## [1] 175
height_girls[-3] ## remove element 3
## [1] 178 175 164 183 192
```

```
height_girls[c(1, 1, 2, 2, 2)] ## open room for bootstraps and more
## [1] 178 175 175 175
```

height_girls[2] ## returns element 2

[1] 175

Subsets can be made (with indexes, booleans or names):

```
height_girls[-3] ## remove element 3

## [1] 178 175 164 183 192

height_girls[c(1, 1, 2, 2, 2)] ## open room for bootstraps and more

## [1] 178 178 175 175 175
```

```
height_girls[height_girls > 168]

## [1] 178 175 183 192

height_girls[!(height_girls == min(height_girls))]

## [1] 178 175 164 183 192

height_girls[height_girls != min(height_girls)]

## [1] 178 175 164 183 192
```

The elements of a vector can be named and those names can be used for subsetting:

```
foo \leftarrow c(alex = 1, colin = 2)
foo
## alex colin
    1 2
foo["colin"]
## colin
## 2
```

The elements of a vector can be named and those names can be used for subsetting:

```
foo <- c(alex = 1, colin = 2)
foo

## alex colin
## 1 2
foo["colin"]
## colin
## 2</pre>
```

But names behave sometimes somewhat unexpectedly:

```
foo[1] + foo[2]
## alex
```

Vectors (as any other object) can have metadata called 'attributes' attached to them:

```
foo <- c(1, 2, 3)
attr(x = foo, which = "whatever") <- "Learning to count"
attr(x = foo, which = "something else?") <- "nope"

foo

## [1] 1 2 3
## attr(, "whatever")
## [1] "Learning to count"
## attr(, "something else?")
## [1] "nope"</pre>
```

Vectors (as any other object) can have metadata called 'attributes' attached to them:

```
foo <- c(1, 2, 3)
attr(x = foo, which = "whatever") <- "Learning to count"
attr(x = foo, which = "something else?") <- "nope"

foo

## [1] 1 2 3
## attr(,"whatever")
## [1] "Learning to count"
## attr(,"something else?")
## [1] "nope"

attr(x = foo, which = "whatever")
## [1] "Learning to count"</pre>
```

Vectors (as any other object) can have metadata called 'attributes' attached to them:

```
foo <-c(1, 2, 3)
attr(x = foo, which = "whatever") <- "Learning to count"</pre>
attr(x = foo, which = "something else?") <- "nope"
foo
## [1] 1 2 3
## attr(,"whatever")
## [1] "Learning to count"
## attr(, "something else?")
## [1] "nope"
attr(x = foo, which = "whatever")
## [1] "Learning to count"
attributes(foo) ## this gives a list, see later!
## $whatever
## [1] "Learning to count"
##
## $`something else?`
## [1] "nope"
```

Note: this is useful to know for handling outputs in certain packages (e.g. spaMM).

Getting started with \boldsymbol{R}

- Introduction
 - Vectors

 - types & classes
 - factors
 - functions
- Matrices and arrays
 - general properties
 - functions
- 4 List
 - general properties
 - functions
- Data frames and tibbles
 - general properties
 - challenge
 - functions
 - dplyr
 - tidyr
 - tibbles
- Importing & exporting data

Types refer to the internal representation of the objects:

logicals

```
(foo <- c(TRUE, FALSE, F, T))
## [1] TRUE FALSE FALSE TRUE

typeof(x = foo)
## [1] "logical"</pre>
```

Types refer to the internal representation of the objects:

logicals

```
(foo <- c(TRUE, FALSE, F, T))
## [1] TRUE FALSE FALSE TRUE

typeof(x = foo)
## [1] "logical"</pre>
```

integers

```
(foo <- c(1L, 5L, 7L, 0L))
## [1] 1 5 7 0

typeof(x = foo)
## [1] "integer"</pre>
```

Types refer to the internal representation of the objects:

logicals

```
(foo <- c(TRUE, FALSE, F, T))
## [1] TRUE FALSE FALSE TRUE
typeof(x = foo)
## [1] "logical"</pre>
```

integers

```
(foo <- c(1L, 5L, 7L, 0L))
## [1] 1 5 7 0

typeof(x = foo)
## [1] "integer"
```

doubles

```
(foo <- c(1, 1.2, pi))

## [1] 1.000000 1.200000 3.141593

typeof(x = foo)

## [1] "double"
```

Types refer to the internal representation of the objects:

logicals

```
(foo <- c(TRUE, FALSE, F, T))
## [1] TRUE FALSE FALSE TRUE

typeof(x = foo)
## [1] "logical"</pre>
```

integers

```
(foo <- c(1L, 5L, 7L, 0L))
## [1] 1 5 7 0
typeof(x = foo)
## [1] "integer"</pre>
```

doubles

```
(foo <- c(1, 1.2, pi))

## [1] 1.000000 1.200000 3.141593

typeof(x = foo)

## [1] "double"
```

characters

```
(foo <- c("bla", "bli", "blo"))
## [1] "bla" "bli" "blo"

typeof(x = foo)
## [1] "character"</pre>
```

Types refer to the internal representation of the objects:

logicals

```
(foo <- c(TRUE, FALSE, F, T))
## [1] TRUE FALSE FALSE TRUE
typeof(x = foo)
## [1] "logical"</pre>
```

integers

```
(foo <- c(1L, 5L, 7L, 0L))
## [1] 1 5 7 0

typeof(x = foo)
## [1] "integer"
```

doubles

```
(foo <- c(1, 1.2, pi))

## [1] 1.000000 1.200000 3.141593

typeof(x = foo)

## [1] "double"
```

characters

```
(foo <- c("bla", "bli", "blo"))
## [1] "bla" "bli" "blo"

typeof(x = foo)
## [1] "character"</pre>
```

Note: **R** detects automatically the type of input and creates the right type of vector for you! Challenge: compare typeof() with mode().

Classes refer to the how functions interact with the objects:

logicals

```
(foo <- c(TRUE, FALSE, F, T))
## [1] TRUE FALSE FALSE TRUE
class(x = foo)
## [1] "logical"</pre>
```

integers

```
(foo <- c(1L, 5L, 7L, 0L))
## [1] 1 5 7 0
class(x = foo)
## [1] "integer"
```

numerics (from the type doubles)

```
(foo <- c(1, 1.2, pi))

## [1] 1.000000 1.200000 3.141593

class(x = foo)

## [1] "numeric"
```

characters

```
(foo <- c("bla", "bli", "blo"))

## [1] "bla" "bli" "blo"

class(x = foo)

## [1] "character"
```

Note: many don't make the distinction between types and classes explicit but it helps to understand some weird behaviours of **R**.

There are more classes than types:

factors

```
(foo <- factor(c("bla", "bli", "blo")))</pre>
## [1] bla bli blo
## Levels: bla bli blo
class(x = foo)
## [1] "factor"
typeof(x = foo)
## [1] "integer"
levels(x = foo)
## [1] "bla" "bli" "blo"
levels(x = foo) <- c(levels(x = foo), "blu") ## set extra level</pre>
table(foo)
## foo
## bla bli blo blu
## 1 1 1 0
```

There are more classes than types:

factors

```
(foo <- factor(c("bla", "bli", "blo")))</pre>
## [1] bla bli blo
## Levels: bla bli blo
class(x = foo)
## [1] "factor"
typeof(x = foo)
## [1] "integer"
levels(x = foo)
## [1] "bla" "bli" "blo"
levels(x = foo) <- c(levels(x = foo), "blu") ## set extra level</pre>
table(foo)
## foo
## bla bli blo blu
## 1 1 1 0
```

dates

There are more classes than types:

factors

```
(foo <- factor(c("bla", "bli", "blo")))</pre>
## [1] bla bli blo
## Levels: bla bli blo
class(x = foo)
## [1] "factor"
typeof(x = foo)
## [1] "integer"
levels(x = foo)
## [1] "bla" "bli" "blo"
levels(x = foo) <- c(levels(x = foo), "blu") ## set extra level
table(foo)
## foo
## bla bli blo blu
## 1 1 1 0
```

dates

Note: factors are heavily used in the context of linear models!

Vectors must contain elements of the same type (otherwise errors or automatic coercion may occur):

```
bar <- "A"
foo_bar <- c(foo, bar)</pre>
foo_bar
## [1] "1" "A"
```

foo <- 1

foo <- 1

Vectors must contain elements of the same type (otherwise errors or automatic coercion may occur):

```
bar <- "A"
foo_bar <- c(foo, bar)
foo_bar
## [1] "1" "A"
foo + 1
## [1] 2
foo_bar[1] + 1
## Error in foo_bar[1] + 1: non-numeric argument to binary operator
```

foo <- 1

Vectors must contain elements of the same type (otherwise errors or automatic coercion may occur):

```
bar <- "A"
foo_bar <- c(foo, bar)
foo_bar
## [1] "1" "A"

foo + 1
## [1] 2
foo_bar[1] + 1</pre>
```

Challenges:

• find out why the previous call produces an error.

Error in foo_bar[1] + 1: non-numeric argument to binary operator

- try to check how the automatic coercion occurs by mixing different classes in different ways (logical, integers, numeric, characters, factors).
- find out which date is internally stored as 0?

16 / 87

Some coercions are straightforward:

```
as.integer(x = 1.2)
## [1] 1
as.integer(x = 1.9)
## [1] 1
as.integer(x = -2.1)
## [1] -2
foo \leftarrow factor(x = 10:20)
foo
## [1] 10 11 12 13 14 15 16 17 18 19 20
## Levels: 10 11 12 13 14 15 16 17 18 19 20
as.character(x = foo)
## [1] "10" "11" "12" "13" "14" "15" "16" "17" "18" "19" "20"
```

Some coercions are straightforward:

```
as.integer(x = 1.2)
## [1] 1
as.integer(x = 1.9)
## [1] 1
as.integer(x = -2.1)
## [1] -2
foo <- factor(x = 10:20)
foo
## [1] 10 11 12 13 14 15 16 17 18 19 20
## Levels: 10 11 12 13 14 15 16 17 18 19 20
as.character(x = foo)
## [1] "10" "11" "12" "13" "14" "15" "16" "17" "18" "19" "20"
But not all:
as.numeric(x = foo)
## [1] 1 2 3 4 5 6 7 8 9 10 11
as.numeric(as.character(x = foo))
## [1] 10 11 12 13 14 15 16 17 18 19 20
foo \leftarrow as.Date(x = "20180618", format = "%Y%m%d")
as.integer(x = foo)
## [1] 17700
as.integer(x = gsub(pattern = "-", replacement = "", x = as.character(foo)))
```

[1] 20180618

factors

Factors

You can create them after in two steps:

```
sex <- c("girl", "girl", "girl", "girl", "girl", "girl",</pre>
"boy", "boy", "boy", "boy")
class(x = sex)
## [1] "character"
sex <- factor(x = sex)
sex
## [1] girl girl girl girl girl boy boy boy
## Levels: boy girl
```

Factors

You can create them after in two steps:

```
sex <- c("girl", "girl", "girl", "girl", "girl", "girl",</pre>
"boy", "boy", "boy", "boy")
class(x = sex)
## [1] "character"
sex <- factor(x = sex)
SAY
## [1] girl girl girl girl girl boy boy boy
## Levels: boy girl
```

Better code:

```
sex <- factor(x = c(rep(x = "girl", times = 6),</pre>
                     rep(x = "bov", times = 4)))
```

Even better code:

```
sex <- factor(x = c(rep(x = "girl", times = length(x = height girls)),</pre>
                     rep(x = "boy", times = length(x = height boys))))
```

Note: more on programming style later!

factors

Combining vectors with different levels

We want to merge the two following vectors:

```
foo <- factor(c("a", "b"))</pre>
## [1] a b
## Levels: a b
bar <- factor(c("b", "c"))
bar
## [1] b c
## Levels: b c
```

factors

Combining vectors with different levels

We want to merge the two following vectors:

```
foo <- factor(c("a", "b"))</pre>
## [1] a b
## Levels: a b
bar <- factor(c("b", "c"))
bar
## [1] b c
## Levels: b c
```

Problem:

```
foo_bar <- c(foo, bar)
foo_bar
## [1] 1 2 1 2
class(foo_bar)
## [1] "integer"
```

Combining vectors with different levels

We want to merge the two following vectors:

```
foo <- factor(c("a", "b"))
## [1] a b
## Levels: a b
bar <- factor(c("b", "c"))</pre>
bar
## [1] b c
## Levels: b c
```

Problem:

```
foo_bar <- c(foo, bar)
foo_bar
## [1] 1 2 1 2
class(foo bar)
## [1] "integer"
```

Solution:

```
foo bar <- factor(c(as.character(foo), as.character(bar)))</pre>
foo_bar
## [1] a b b c
## Levels: a b c
class(foo_bar)
## [1] "factor"
```

Dropping unused levels

By default **R** keeps unused levels:

```
foo <- factor(c("a", "a", "b", "c"))
foo
## [1] a a b c
## Levels: a b c
table(foo)
## foo
## a b c
## 2 1 1
bar <- foo[-4]
table(bar)
## bar
## a b c
## 2 1 0
```

Dropping unused levels

By default **R** keeps unused levels:

```
foo <- factor(c("a", "a", "b", "c"))
foo
## [1] a a b c
## Levels: a b c
table(foo)
## foo
## a b c
## 2 1 1
bar <- foo[-4]
table(bar)
## bar
## a b c
## 2 1 0</pre>
```

If you want to update the levels you need to use the function droplevels:

```
new_bar <- droplevels(bar)
table(new_bar)
## new_bar
## a b
## 2 1</pre>
```

Or use the argument drop:

```
bar <- foo[-4, drop = TRUE]
table(bar)
## bar
## a b
## 2 1</pre>
```

Changing the order of levels of a factor

You have:

my_factor1 ## [1] A A B B C ## Levels: A B C

You want:

my_factor2 ## [1] A A B B C ## Levels: C B A

Changing the order of levels of a factor

You have:

You want:

my_factor1										
##	[1]	Α	Α	В	В	С				
##	Levels:			Α	В	С				

```
my_factor2
## [1] A A B B C
## Levels: C B A
```

You do:

```
my_factor2 <- factor(x = my_factor1, levels = levels(my_factor1)[c(3, 2, 1)])</pre>
my_factor2
## [1] A A B B C
## Levels: C B A
```

Changing the order of levels of a factor

You have:

You want:

my_factor1											
	[1] Leve										

```
my_factor2
## [1] A A B B C
## Levels: C B A
```

You do:

```
my_factor2 <- factor(x = my_factor1, levels = levels(my_factor1)[c(3, 2, 1)])</pre>
my_factor2
## [1] A A B B C
## Levels: C B A
```

Or if you only care about the first level:

```
my_factor3 <- relevel(x = my_factor1, ref = "C")</pre>
my_factor3
## [1] A A B B C
## Levels: C A B
```

Changing the order of levels of a factor

You have: my_factor1 ## [1] A A B B C ## Levels: A B C

You want:

my_factor2 ## [1] A A B B C ## Levels: C B A

You do:

```
my_factor2 <- factor(x = my_factor1, levels = levels(my_factor1)[c(3, 2, 1)])
my_factor2
## [1] A A B B C
## Levels: C B A</pre>
```

Or if you only care about the first level:

```
my_factor3 <- relevel(x = my_factor1, ref = "C")
my_factor3
## [1] A A B B C
## Levels: C A B</pre>
```

Note: the order of levels influences the meaning of parameter estimates in linear models and some plotting functions (e.g. order in the legend of a ggplot) . . .

Changing the levels of a factor

You have:

my_factor1 ## [1] A A B B C ## Levels: A B C

You want:

my_factor2 ## [1] A A A A D ## Levels: A D

Changing the levels of a factor

You have:

You want:

my_factor1 ## [1] A A B B C ## Levels: A B C

my_factor2 ## [1] A A A A D ## Levels: A D

You do:

```
## Using base:
levels(x = my_factor1)
## [1] "A" "B" "C"
my_factor2 <- my_factor1
levels(x = my_factor2) <- c("A", "A", "D") ## in same order!</pre>
my_factor2
## [1] A A A A D
## Levels: A D
```

Changing the levels of a factor

You have:

You want:

my_factor1 ## [1] A A B B C ## Levels: A B C

my_factor2 ## [1] A A A A D ## Levels: A D

You do:

```
## Using base:
levels(x = my_factor1)
## [1] "A" "B" "C"
my_factor2 <- my_factor1
levels(x = my_factor2) <- c("A", "A", "D") ## in same order!</pre>
my_factor2
## [1] A A A A D
## Levels: A D
## Using dplyr:
library(dplyr)
my_factor2 <- recode(.x = my_factor1, A = "A", B = "A", C = "D")</pre>
my_factor2
## [1] A A A A D
## Levels: A D
```

Changing the levels of a factor

You have: my_factor1 ## [1] A A B B C ## Levels: A B C

You want:

my_factor2 ## [1] A A A A D ## Levels: A D

You do:

```
## Using base:
levels(x = my_factor1)
## [1] "A" "B" "C"
my_factor2 <- my_factor1
levels(x = my_factor2) <- c("A", "A", "D") ## in same order!</pre>
my_factor2
## [1] A A A A D
## Levels: A D
## Using dplyr:
library(dplyr)
my_factor2 <- recode(.x = my_factor1, A = "A", B = "A", C = "D")</pre>
my_factor2
## [1] A A A A D
## Levels: A D
```

Note: if you want more modern functions to manipulate factors, look at the package forcats from tidyverse.

sapply() is a function to apply a function on each element of a vector:

```
triple <- function(x) c(x, x, x) ## let us create a silly function
triple(x = "a")
## [1] "a" "a" "a"
sapply(X = bar, FUN = triple) ## here returns a matrix (automatic choice)
                    [,3] [,4]
       [,1] [,2]
       1 1.2 3.141593 NA
## [1,]
## [2,] 1 1.2 3.141593
## [3.] 1 1.2 3.141593 NA
```

sapply() is a function to apply a function on each element of a vector:

```
triple <- function(x) c(x, x, x) ## let us create a silly function
triple(x = "a")
## [1] "a" "a" "a"
sapply(X = bar, FUN = triple) ## here returns a matrix (automatic choice)
        [,1] [,2]
                     [.3] [.4]
        1 1.2 3.141593
## [1,]
## [2,] 1 1.2 3.141593
## [3.] 1 1.2 3.141593 NA
sapply(X = bar, FUN = triple, simplify = FALSE) ## same but always returns a list
## [[1]]
## [1] 1 1 1
##
## [[2]]
## [1] 1.2 1.2 1.2
## [[3]]
## [1] 3.141593 3.141593 3.141593
## [[4]]
## [1] NA NA NA
```

sapply() is a function to apply a function on each element of a vector:

```
triple <- function(x) c(x, x, x) ## let us create a silly function
triple(x = "a")
## [1] "a" "a" "a"
sapply(X = bar, FUN = triple) ## here returns a matrix (automatic choice)
        [,1] [,2]
                     [.3] [.4]
## [1,]
        1 1.2 3.141593
## [2.]
        1 1.2 3.141593
## [3,] 1 1.2 3.141593
                           NΑ
sapply(X = bar, FUN = triple, simplify = FALSE) ## same but always returns a list
## [[1]]
## [1] 1 1 1
## [[2]]
## [1] 1.2 1.2 1.2
## [[3]]
## [1] 3.141593 3.141593 3.141593
## [[4]]
## [1] NA NA NA
```

Note 1: this is useful when the function cannot work on vector and when the return is more than one element. For example, the input could be a vector of file names and the output one dataset per file!

sapply() is a function to apply a function on each element of a vector:

```
triple <- function(x) c(x, x, x) ## let us create a silly function
triple(x = "a")
## [1] "a" "a" "a"
sapply(X = bar, FUN = triple) ## here returns a matrix (automatic choice)
        [,1] [,2]
                     [.3] [.4]
## [1,]
        1 1.2 3.141593
## [2.]
        1 1.2 3.141593
## [3,] 1 1.2 3.141593
                           NΑ
sapply(X = bar, FUN = triple, simplify = FALSE) ## same but always returns a list
## [[1]]
## [1] 1 1 1
## [[2]]
## [1] 1.2 1.2 1.2
## [[3]]
## [1] 3.141593 3.141593 3.141593
## [[4]]
## [1] NA NA NA
```

Note 1: this is useful when the function cannot work on vector and when the return is more than one element.

For example, the input could be a vector of file names and the output one dataset per file!

Note 2: if you want more modern functions more consistent than the *apply() ones, look at the package purrr from tidyverse.

sapply() is a function to apply a function on each element of a vector:

```
triple <- function(x) c(x, x, x) ## let us create a silly function
triple(x = "a")
## [1] "a" "a" "a"
sapply(X = bar, FUN = triple) ## here returns a matrix (automatic choice)
        [,1] [,2]
                      [,3] [,4]
## [1,]
         1 1.2 3.141593
## [2.]
        1 1.2 3.141593
## [3.]
       1 1.2 3.141593
sapply(X = bar, FUN = triple, simplify = FALSE) ## same but always returns a list
## [[1]]
## [1] 1 1 1
## [[2]]
## [1] 1.2 1.2 1.2
## [[3]]
## [1] 3.141593 3.141593 3.141593
## [[4]]
## [1] NA NA NA
```

Note 1: this is useful when the function cannot work on vector and when the return is more than one element.

For example, the input could be a vector of file names and the output one dataset per file!

Note 2: if you want more modern functions more consistent than the *apply() ones, look at the package purrr from tidyverse.

Challenge: can you think of an alternative to do that without using sapply()?

Getting started with **R**

- Matrices and arrays
- 4 List

Matrices & arrays

The matrices and arrays are direct extentions of vectors when there is more than one dimension (1 or 2 dimensions for matrices, any for arrays).

Example of a matrix:

```
my_matrix <- matrix(data = 1:12, ncol = 4, nrow = 3)
my_matrix

## [,1] [,2] [,3] [,4]
## [1,] 1 4 7 10
## [2,] 2 5 8 11
## [3,] 3 6 9 12

class(x = my_matrix)
## [1] "matrix"

typeof(x = my_matrix) ## behind the curtain, matrices are stored as vectors!
## [1] "integer"</pre>
```

Matrices & arrays

The matrices and arrays are direct extentions of vectors when there is more than one dimension (1 or 2 dimensions for matrices, any for arrays).

Example of a matrix:

```
my_matrix <- matrix(data = 1:12, ncol = 4, nrow = 3)
my_matrix

## [,1] [,2] [,3] [,4]
## [1,] 1 4 7 10
## [2,] 2 5 8 11
## [3,] 3 6 9 12

class(x = my_matrix)

## [1] "matrix"

typeof(x = my_matrix) ## behind the curtain, matrices are stored as vectors!

## [1] "integer"</pre>
```

Note 1: since there are a kind of vectors, the same restrictions apply: all elements must have the same class! Note 2: useful for building the input of some statistical tests (e.g. chi-square), for linear algebra (e.g. computation behind linear models), for handling GIS information & for understanding data frames.

Getting started with \boldsymbol{R}

- Introduction
- Vectors
 - general properties
 - types & classes
 - factors
 - functions
- Matrices and arrays
 - general properties
 - functions
- 4 List
 - general properties

- Importing & exporting data

They can be combined:

```
(my_2nd_matrix <- matrix(data = 13:18, ncol = 2, nrow = 3))</pre>
       [,1] [,2]
## [1,] 13 16
## [2,] 14 17
## [3,] 15 18
(my_3rd_matrix <- matrix(data = 1:4, nrow = 1))</pre>
       [,1] [,2] [,3] [,4]
## [1,] 1 2 3 4
```

(my_2nd_matrix <- matrix(data = 13:18, ncol = 2, nrow = 3))</pre>

They can be combined:

```
[,1] [,2]
## [1,] 13 16
## [2,] 14 17
## [3,] 15 18
(my_3rd_matrix <- matrix(data = 1:4, nrow = 1))</pre>
## [,1] [,2] [,3] [,4]
## [1,] 1 2 3 4
cbind(my_matrix, my_2nd_matrix) ## bind columns
## [,1] [,2] [,3] [,4] [,5] [,6]
## [1.]
      1 4 7 10
                       13 16
## [2,] 2 5 8 11 14 17
## [3,] 3 6 9 12 15 18
```

They can be combined:

```
(my_2nd_matrix <- matrix(data = 13:18, ncol = 2, nrow = 3))</pre>
       [,1] [,2]
## [1,] 13 16
## [2,] 14 17
## [3,] 15 18
(my_3rd_matrix <- matrix(data = 1:4, nrow = 1))</pre>
## [,1] [,2] [,3] [,4]
## [1,] 1 2 3 4
cbind(my_matrix, my_2nd_matrix) ## bind columns
## [,1] [,2] [,3] [,4] [,5] [,6]
## [1,] 1 4 7 10
                         13 16
## [2,] 2 5 8 11 14 17
## [3,] 3 6 9 12 15 18
rbind(my_matrix, my_3rd_matrix) ## bind rows
       [,1] [,2] [,3] [,4]
## [1,] 1 4 7 10
## [2,] 2 5 8 11
## [3,] 3 6 9 12
## [4.]
```

Subsets can be made (with indexes, booleans or names):

```
my_matrix[2, ]
## [1] 2 5 8 11
my_matrix[, 1]
## [1] 1 2 3
my_matrix[3, , drop = FALSE] ## to keep a matrix
## [,1] [,2] [,3] [,4]
## [1,] 3 6 9 12
my_matrix[2, 1]
## [1] 2
my_matrix[c(1:2), c(1:2)]
## [,1] [,2]
## [1,] 1 4
## [2,] 2 5
```

Subsets can be made (with indexes, booleans or names):

```
my_matrix[2, ]
## [1] 2 5 8 11
my_matrix[, 1]
## [1] 1 2 3
my_matrix[3, , drop = FALSE] ## to keep a matrix
## [,1] [,2] [,3] [,4]
## [1,] 3 6 9 12
my_matrix[2, 1]
## [1] 2
my_matrix[c(1:2), c(1:2)]
## [,1] [,2]
## [1,] 1 4
## [2,] 2 5
colnames(x = my_matrix) <- c("A", "B", "C", "D")</pre>
rownames(x = my_matrix) <- c("a", "b", "c")
my_matrix
## A B C D
## a 1 4 7 10
## b 2 5 8 11
## c 3 6 9 12
my_matrix["b", ]
## A B C D
## 2 5 8 11
```

attributes(my_matrix)

In the background, a matrix is a vector with dimension attributes (i.e. number of columns and rows).

```
## $dim
## [1] 3 4
## $dimnames
## $dimnames[[1]]
## [1] "a" "b" "c"
## $dimnames[[2]]
## [1] "A" "B" "C" "D"
str(my_matrix)
## int [1:3, 1:4] 1 2 3 4 5 6 7 8 9 10 ...
## - attr(*, "dimnames")=List of 2
## ..$ : chr [1:3] "a" "b" "c"
## ..$ : chr [1:4] "A" "B" "C" "D"
```

In the background, a matrix is a vector with dimension attributes (i.e. number of columns and rows).

```
attributes(my_matrix)
## $dim
## [1] 3 4
## $dimnames
## $dimnames[[1]]
## [1] "a" "b" "c"
## $dimnames[[2]]
## [1] "A" "B" "C" "D"
str(my_matrix)
## int [1:3, 1:4] 1 2 3 4 5 6 7 8 9 10 ...
## - attr(*, "dimnames")=List of 2
## ..$ : chr [1:3] "a" "b" "c"
## ..$: chr [1:4] "A" "B" "C" "D"
```

You can subset the data using this dimension attributes or not:

```
my_matrix[5]
## [1] 5
my_matrix[2, 2]
## [1] 5
```

attributes(my_matrix)

In the background, a matrix is a vector with dimension attributes (i.e. number of columns and rows).

```
## $dim
## [1] 3 4
## $dimnames
## $dimnames[[1]]
## [1] "a" "b" "c"
## $dimnames[[2]]
## [1] "A" "B" "C" "D"
str(my_matrix)
## int [1:3, 1:4] 1 2 3 4 5 6 7 8 9 10 ...
## - attr(*, "dimnames")=List of 2
## ..$ : chr [1:3] "a" "b" "c"
## ..$: chr [1:4] "A" "B" "C" "D"
```

You can subset the data using this dimension attributes or not:

```
my_matrix[5]
## [1] 5
my_matrix[2, 2]
## [1] 5
```

A matrix will be filled from top - bottom, left - right:

```
(my matrix4 <- matrix(data = 1:4, ncol = 2, nrow = 2)) ## but try burow = TRUE
       [,1] [,2]
## [1,]
       1 3
## [2,]
```

Getting started with R

- Introduction
 - Vectors
 - general properties
 - types & classes
 - factors
 - functions
- Matrices and arrays
 - general properties
 - functions
- List
 - general properties
 - functions
- Data frames and tibbles
 - general properties
 - challenge
 - functions
 - dplyr
 - tidyr
 - tibbles
- Importing & exporting data

Some simple functions for matrices

Dimensions:

```
dim(x = my_matrix)
## [1] 3 4
ncol(x = my_matrix)
## [1] 4
nrow(x = my_matrix)
## [1] 3
length(x = my_matrix)
## [1] 12
```

Names:

```
colnames(x = my_matrix)
## [1] "A" "B" "C" "D"
rownames(x = my_matrix)
## [1] "a" "b" "c"
```

Linear algebra:

```
t(x = my_matrix) ## transpose

## a b c

## A 1 2 3

## B 4 5 6

## C 7 8 9

## D 10 11 12

my_matrix %*% c(1:4) ## matrix multiplication

## [,1]

## a 70

## b 80

## c 90

diag(x = my_matrix) ## extract diagonal

## [1] 1 5 9
```

apply() is a function to apply a function on each row or column of a matrix:

```
apply(X = my_matrix, MARGIN = 1, FUN = mean) ## row means
## 5.5 6.5 7.5
apply(X = my_matrix, MARGIN = 2, FUN = sd) ## column SDs
## A B C D
## 1 1 1 1
```

Arrays?

Arrays are very similar to matrices but allow for more dimensions:

```
foo \leftarrow array(data = 1:8, dim = c(2, 2, 2))
foo
## , , 1
    [,1] [,2]
## [1,] 1 3
## [2,]
## , , 2
       [,1] [,2]
## [1,] 5 7
## [2,] 6 8
```

```
foo[1, 2, 2]
## [1] 7
apply(X = foo, MARGIN = 3, FUN = sum)
## [1] 10 26
```

Note: only useful in some very specific situations.

Getting started with **R**

- Introduction
- 2 Vectors
- Matrices and arrays
- 4 List
- Data frames and tibbles
- Importing & exporting data

Lists

Lists allow the organisation of any set of entities into a single R object.

Example of a list:

```
list_height <- list(height_girls, height_boys)
list_height
## [[1]
## [[1] 178 175 159 164 183 192
##
## [[2]]
## [1] 181 189 174 177
class(x = list_height)
## [1] "list"
typeof(x = list_height)
## [1] "list"</pre>
```

Note 1: list elements can be anything!

Note 2: lists are very important because no function can output more than one object!

Getting started with \boldsymbol{R}

- Introduction
 - 2 Vectors

 - types & classes
 - factors
 - functions
- Matrices and arrays
 - general properties
 - functions
- 4 List
 - general properties
 - functions
- Data frames and tibbles
 - general properties
 - challenge
 - functions
 - dplyr
 - tidyr
 - tibbles
- Importing & exporting data

Lists: general properties

They can be combined:

```
list_full <- c(list_height, list(my_matrix))</pre>
list_full
## [[1]]
## [1] 178 175 159 164 183 192
##
## [[2]]
## [1] 181 189 174 177
## [[3]]
## A B C D
## a 1 4 7 10
## b 2 5 8 11
## c 3 6 9 12
```

Lists: general properties

Subsets can be made (with indexes, booleans or names):

```
list_height <- list(girls = height_girls, boys = height_boys) ## create a list with names</pre>
list_height
## $girls
## [1] 178 175 159 164 183 192
##
## $boys
## [1] 181 189 174 177
list_height$girls
## [1] 178 175 159 164 183 192
list_height["boys"] ## still a list
## $bovs
## [1] 181 189 174 177
list_height[["boys"]] ## vector
## [1] 181 189 174 177
list_height[[2]][3]
## [1] 174
```

Getting started with ${\bf R}$

- Introduction
 - 2 Vectors
 - general properties
 - types & classes
 - factors
 - functions
- Matrices and arrays
 - general properties
 - functions
- 4 List
 - general properties
 - functions
- Data frames and tibbles
 - general properties
 - challenge
 - functions
 - dplyr
 - tidyr
 - tibbles
- Importing & exporting data

Some simple functions for lists

```
length(x = list_full) ## number of elements
## [1] 3
str(object = list_full) ## this function is really useful!
## List of 3
## $ : num [1:6] 178 175 159 164 183 192
## $ : num [1:4] 181 189 174 177
## $ : int [1:3, 1:4] 1 2 3 4 5 6 7 8 9 10 ...
## ..- attr(*, "dimnames")=List of 2
## ....$ : chr [1:3] "a" "b" "c"
    .. ..$ : chr [1:4] "A" "B" "C" "D"
```

Challenge: run the examples from lm() and explore the list lm.D9.

A more complex function: lapply()

lapply() is a function to apply a function on each element of a list:

```
lapply(X = list_full, FUN = mean)
## [[1]]
## [1] 175.1667
## [[2]]
## [1] 180.25
## [[3]]
## [1] 6.5
```

Getting started with **R**

- 4 List
- Data frames and tibbles

Data frames

Data frames allow the organisation of vectors of the same length as a matrix-like structure:

Example:

```
dataframe_ht <- data.frame(Height = height, Sex = sex)</pre>
dataframe_ht
      Height Sex
## 1
         181 girl
## 2
        189 girl
## 3
        174 girl
        177 girl
## 5
         178 girl
        175 girl
## 7
        159 boy
## 8
        164 boy
## 9
         183 boy
## 10
         192 boy
class(dataframe_ht)
## [1] "data.frame"
typeof(dataframe_ht)
## [1] "list"
```

Data frames

Data frames allow the organisation of vectors of the same length as a matrix-like structure:

Example:

```
dataframe_ht <- data.frame(Height = height, Sex = sex)
dataframe ht
      Height Sex
## 1
         181 girl
## 2
        189 girl
## 3
        174 girl
        177 girl
## 4
## 5
         178 girl
## 6
        175 girl
## 7
        159 boy
## 8
         164 boy
## 9
         183 bov
## 10
         192 boy
class(dataframe_ht)
## [1] "data.frame"
typeof(dataframe_ht)
## [1] "list"
```

Note 1: this is the best choice of representation for datasets!

Note 2: it is safer to work on data frames than on floating vectors!

## 6
```

Using the iris data frame, find out:

- what is the average sepal length across all flowers?
- what is the median sepal length across *Iris versicolor*?

Data frames can easily be edited:

```
backup <- dataframe_ht[1, 1]</pre>
dataframe_ht[1, 1] <- 171.3
dataframe_ht[1, 1]
## [1] 171.3
dataframe_ht[1, 1] <- backup
dataframe_ht[1, 1]
## [1] 181
```

Data frames can easily be edited:

```
backup <- dataframe_ht[1, 1]
dataframe_ht[1, 1] <- 171.3
dataframe_ht[1, 1]
## [1] 171.3
dataframe_ht[1, 1] <- backup
dataframe_ht[1, 1]
## [1] 181
dataframe_ht$linenumber <- 1:nrow(x = dataframe_ht) # add column
head(x = dataframe_ht)
    Height Sex linenumber

   Max. :7.900
                   Max.
                          :4.400
                                   Max.
                                          :6.900
                                                    Max.
                                                          :2.500
```

```
dim(x = iris)
## [1] 150    5
ncol(x = iris)
## [1] 5
nrow(x = iris)
## [1] 150
length(x = iris) ## not as in matrix!!
## [1] 5
rownames(x = iris) [1:10]
## [1] "1" "2" "3" "4" "5" "6" "7" "8" "9" "10"
colnames(x = iris)
## [1] "Sepal.Length" "Sepal.Width" "Petal.Length" "Petal.Width"
```

A more complex function: tapply()

tapply() is a function to apply a function on subsets of a given column from the data frame:

```
tapply(X = iris$Sepal.Length, INDEX = iris$Species, FUN = mean)
##     setosa versicolor virginica
##     5.006     5.936     6.588
```

A more complex function: tapply()

tapply() is a function to apply a function on subsets of a given column from the data frame:

```
tapply(X = iris$Sepal.Length, INDEX = iris$Species, FUN = mean)
      setosa versicolor virginica
##
       5.006
                  5.936
                              6.588
```

Or similarly:

```
with(data = iris, tapply(X = Sepal.Length, INDEX = Species, FUN = mean))
      setosa versicolor virginica
##
       5.006
                  5.936
                              6.588
##
```

A more complex function: tapply()

tapply() is a function to apply a function on subsets of a given column from the data frame:

```
tapply(X = iris$Sepal.Length, INDEX = iris$Species, FUN = mean)
## setosa versicolor virginica
## 5.006 5.936 6.588
```

Or similarly:

```
with(data = iris, tapply(X = Sepal.Length, INDEX = Species, FUN = mean))
## setosa versicolor virginica
## 5.006 5.936 6.588
```

Or similarly:

Note: by() is more powerful but more complex than tapply().

The dplyr alternative to tapply()

The same operation in dplyr looks very different:

```
iris %>%
  group_by(Species) %>%
  summarize(mean_sepal_length = mean(Sepal.Length),
            mean sepal width = mean(Sepal.Width)) %>%
  as.data.frame() ## optional but otherwise tibble and not data frame
        Species mean sepal length mean sepal width
## 1
         setosa
                            5.006
                                             3.428
## 2 versicolor
                            5.936
                                             2.770
                            6.588
                                             2.974
## 3 virginica
```

Note: this replaces two tapply() calls and remains easy to read.

Getting started with \boldsymbol{R}

- Introduction
- 2 Vectors

- Importing & exporting data

dplyr is part of the growing tidyverse world (https://www.tidyverse.org/) developped by RStudio:

dplyr is part of the growing tidyverse world (https://www.tidyverse.org/) developped by RStudio:

R core team

- build the core of R and the original R GUI
- maintain CRAN
- backward compatibility is the priority
- limited man power (20 selected volunteers)
- not commercial (but Microsoft may creep in?)

RStudio

- build RStudio IDE, tidyverse and more
- tidyverse philosophy: 1 function = 1 action
- backward compatibility is not the priority
- 1 leader (Hadley Wickham) $+ \sim 70$ full time employees + tons of volunteers
- free + commercial

dplyr is part of the growing tidyverse world (https://www.tidyverse.org/) developped by RStudio:

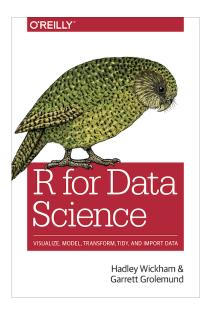

R core team

- build the core of R and the original R GUI
- maintain CRAN
- backward compatibility is the priority
- limited man power (20 selected volunteers)
- not commercial (but Microsoft may creep in?)
- Note 1: that has led to two quite distinct R dialects
- Note 2: more and more users rely on tidyverse...
- Note 3: we will see a bit of both dialects

RStudio

- build RStudio IDE, tidyverse and more
- tidyverse philosophy: 1 function = 1 action
- backward compatibility is not the priority
- ullet 1 leader (Hadley Wickham) $+\sim$ 70 full time employees + tons of volunteers
- free + commercial

dplyr

- in dplyr one verb = one action = one function (tidyverse philosophy)
- operations can be chained with the pipe operator %>% (from package magrittr), which considers the output from one function as the input of the next function

dplyr

- in dplyr one verb = one action = one function (tidyverse philosophy)
- operations can be chained with the pipe operator %>% (from package magrittr), which considers the output from one function as the input of the next function

Pros

- clear code
- consistent
- powerful
- fast
- many tutorials

dplyr

- in dplyr one verb = one action = one function (tidyverse philosophy)
- operations can be chained with the pipe operator %>% (from package magrittr), which considers the output from one function as the input of the next function

Pros

- clear code
- consistent
- powerful
- fast
- many tutorials

Cons

- different & redundant
- buggy (but less & less so)
- poor traditional documentation
- lead to bad habits (e.g. arguments not named, help not looked at)
- broaden the gap between users and programmers

dplyr verbs

Useful dplyr functions:

• add column with mutate()

```
dataframe_ht <- dataframe_ht %>% mutate(ID = 1:nrow(dataframe_ht))
head(x = dataframe_ht, n = 3)
    Height Sex ID
## 1 181 girl 1
     189 girl 2
## 3
     174 girl 3
```

dplyr verbs

Useful dplyr functions:

• add column with mutate()

```
dataframe_ht <- dataframe_ht %>% mutate(ID = 1:nrow(dataframe_ht))
head(x = dataframe_ht, n = 3)
    Height Sex ID
## 1 181 girl 1
## 2 189 girl 2
## 3 174 girl 3
```

• change column with transmute()

```
dataframe_ht2 <- dataframe_ht %>% transmute(double_height = 2*height)
head(x = dataframe_ht2, n = 3)
    double_height
## 1
              362
## 2
              378
## 3
               348
```

dplyr verbs

Useful dplyr functions:

• select columns with select()

```
dataframe_ht_sex <- dataframe_ht %>% select(Sex)
head(x = dataframe_ht_sex, n = 3)
     Sex
## 1 girl
## 2 girl
## 3 girl
```

dplyr verbs

Useful dplyr functions:

select columns with select()

```
dataframe_ht_sex <- dataframe_ht %>% select(Sex)
head(x = dataframe ht sex, n = 3)
      Sex
## 1 girl
## 2 girl
## 3 girl
```

• select rows with filter()

```
dataframe_ht_female <- dataframe_ht %>% filter(Sex == "girl")
head(dataframe_ht_female, n = 3)
    Height Sex ID
## 1 181 girl 1
      189 girl 2
## 3
      174 girl 3
```

dplyr verbs

Useful dplyr functions:

select columns with select()

```
dataframe ht sex <- dataframe ht %>% select(Sex)
head(x = dataframe ht sex. n = 3)
     Sex
## 1 girl
## 2 girl
## 3 girl
```

select rows with filter()

```
dataframe_ht_female <- dataframe_ht %>% filter(Sex == "girl")
head(dataframe_ht_female, n = 3)
    Height Sex ID
## 1 181 girl 1
## 2
     189 girl 2
## 3
     174 girl 3
```

sort rows with arrange()

```
dataframe_ht_sorted <- dataframe_ht %>% arrange(Height) ## add arrange(desc(Height)) for the other direction
head(dataframe_ht_sorted, n = 3)
    Height Sex ID
## 1
      159 boy 7
## 2
      164 bov 8
      174 girl 3
## 3
```

Around dplyr verbs

These main dplyr functions have derivatives and some of them can be useful: e.g. mutate_if performs mutation if a condition is fulfilled, which could be useful for example if you want to change all numeric variables into character variables:

you have:

you want:

```
## 'data.frame': 150 obs. of 5 variables:
## 'data.frame': 150 obs. of 5 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
                                                                 ## $ Sepal.Length: chr "5.1" "4.9" "4.7" "4.6" ...
                                                                 ## $ Sepal.Width : chr "3.5" "3" "3.2" "3.1" ...
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
                                                                 ## $ Petal.Length: chr "1.4" "1.4" "1.3" "1.5" ...
## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
                                                                 ## $ Petal.Width : chr "0.2" "0.2" "0.2" "0.2" ...
## $ Species : Factor w/ 3 levels "setosa". "versicolor"...: 1
                                                                 ## $ Species : Factor w/ 3 levels "setosa". "versicolor"...: 1 1
```

you do:

```
iris_numeric <- iris %>%
  mutate if(is.numeric, ~ as.character(.))
```

The $group_by()$ function allows you to perform operation on grouped data.

The group_by() function allows you to perform operation on grouped data.

It is very powerful when combined to:

ullet summarize() o one value per group

The group_by() function allows you to perform operation on grouped data.

It is very powerful when combined to:

ullet summarize() o one value per group

mutate() or transmute() → one value per observation

The group_by() function allows you to perform operation on grouped data.

It is very powerful when combined to:

summarize() → one value per group

mutate() or transmute() → one value per observation

ullet slice() o select some rows for each "group"

group_by() with summarize()

Example: you want the mean height of males and females, the median height and the number in each group:

```
dataframe_ht %>%
  group_by(Sex) %>%
  summarize(mean height = mean(Height),
            median_height = median(Height),
            n = n()) \% \%
 as.data.frame()
     Sex mean_height median_height n
## 1
     bov
               174.5
                             173.5 4
                             177.5 6
## 2 girl
               179.0
```

group_by() with mutate()

Same as before, but we want to repeat the value for each individual:

```
dataframe_ht %>%
  group_by(Sex) %>%
  mutate(mean_height = mean(Height),
           median_height = median(Height),
           n = n()) \% \%
  as.data.frame()
      Height Sex ID mean_height median_height n
        181 girl 1
                          179.0
                                        177.5 6
## 1
        189 girl 2
## 2
                          179.0
                                        177.5 6
## 3
        174 girl 3
                          179.0
                                       177.5 6
        177 girl 4
                          179.0
                                       177.5 6
## 4
## 5
        178 girl 5
                        179.0
                                       177.5 6
## 6
        175 girl 6
                          179.0
                                      177.5 6
## 7
        159 boy 7
                          174.5
                                       173.5 4
## 8
        164 boy 8
                          174.5
                                       173.5 4
        183 boy 9
                          174.5
                                       173.5 4
## 9
        192 boy 10
                          174.5
                                        173.5 4
## 10
```

Note: many other functions than n() can be used, see ?summarise !

group_by() with slice()

Example: you want the first two rows of each species of irices:

```
iris %>%
 group_by(Species) %>%
 slice(1:2) %>%
 as.data.frame()
    Sepal.Length Sepal.Width Petal.Length Petal.Width
                                                     Species
## 1
            5.1
                       3.5
                                   1.4
                                              0.2
                                                      setosa
## 2
            4.9
                       3.0
                                   1.4
                                              0.2
                                                      setosa
            7.0
                       3.2
                                   4.7
                                              1.4 versicolor
            6.4
                    3.2
                             4.5
                                              1.5 versicolor
            6.3
                       3.3
                                   6.0
                                               2.5 virginica
## 6
            5.8
                       2.7
                                   5.1
                                               1.9 virginica
```

Challenge

Use the dataset called population_UK and compute the total population size for:

- 1915
- 2015
- all years in the dataset
- all years between 1915 and 2015

Use the dataset called deaths_UK and figure out:

- which were the top 3 detailed causes of death before 1930 for each of the 21 broader categories
- the death toll for all individuals below 15 yrs for each year

Data frame #1:

```
my_df1 <- iris %>%
 filter(Species == "setosa") %>%
  select(Sepal.Length, Petal.Length, Species) %>%
  slice(1:4)
mv_df1[4, 1] <- NA
my_df1
    Sepal.Length Petal.Length Species
             5.1
                         1.4 setosa
## 2
             4.9
                        1.4 setosa
             4.7
                        1.3 setosa
## 3
## 4
              NA
                        1.5 setosa
```

Data frame #2:

```
my_df2 <- iris %>%
  filter(Species == "virginica") %>%
  select(Sepal.Length, Petal.Width, Species) %>%
 slice(1:4)
mv_df2[3, 2] <- NA
my_df2
    Sepal.Length Petal.Width
                               Species
             6.3
## 1
                         2.5 virginica
## 2
             5.8
                        1.9 virginica
## 3
             7.1
                        NA virginica
             6.3
                         1.8 virginica
## 4
```

We will see how to merge these two data frames!

There are several options but full_join() is the most effective one: it keeps all the rows of the two data frames and adds NA when no data are present!

```
mv df3 <- full join(mv df1, mv df2)
## Joining, by = c("Sepal.Length", "Species")
my_df3
    Sepal.Length Petal.Length
                               Species Petal.Width
## 1
             5.1
                         1.4 setosa
## 2
             4.9
                         1.4 setosa
                                                NA
             4.7
                         1.3 setosa
                                               NA
## 3
                         1.5 setosa
## 4
            NA
                                               NA
             6.3
                          NA virginica
                                              2.5
## 5
## 6
             5.8
                          NA virginica
                                              1.9
## 7
            7.1
                          NA virginica
                                              NA
             6.3
                          NA virginica
## 8
                                              1.8
```

Note: you can also do that without dplyr but the outcome is a bit more messy:

```
merge(my_df1, my_df2, all = TRUE)
```

You can also use left_join() to keep all data from the first dataset and keep only the new data from the second data set that fit in:

```
(flower_quality <- data.frame(Species = c("setosa", "versicolor", "virginica"),
                             Quality = c("High", "Medium", "Low")))
       Species Quality
        setosa
                  High
## 2 versicolor Medium
## 3 virginica
                   Low
```

You can also use left_join() to keep all data from the first dataset and keep only the new data from the second data set that fit in:

```
(flower_quality <- data.frame(Species = c("setosa", "versicolor", "virginica"),
                             Quality = c("High", "Medium", "Low")))
        Species Quality
         setosa
                   High
## 2 versicolor Medium
## 3 virginica
                   Low
left_join(my_df3, flower_quality, by = "Species")
     Sepal.Length Petal.Length Species Petal.Width Quality
## 1
              5.1
                               setosa
                                                       High
## 2
                          1.4 setosa
              4.9
                                                      High
## 3
             4.7
                          1.3 setosa
                                                      High
## 4
             NA
                          1.5 setosa
                                                      High
## 5
             6.3
                           NA virginica
                                                2.5
                                                      Low
             5.8
                           NA virginica
## 6
                                               1.9
                                                        Low
## 7
             7.1
                           NA virginica
                                                NA
                                                        Low
## 8
             6.3
                           NA virginica
                                                1.8
                                                        Low
```

You can also use left_join() to keep all data from the first dataset and keep only the new data from the second data set that fit in:

```
(flower_quality <- data.frame(Species = c("setosa", "versicolor", "virginica"),
                               Quality = c("High", "Medium", "Low")))
        Species Quality
         setosa
                   High
## 2 versicolor Medium
## 3 virginica
                    Low
left_join(my_df3, flower_quality, by = "Species")
     Sepal.Length Petal.Length
                                 Species Petal.Width Quality
## 1
              5.1
                                  setosa
                                                          High
## 2

Challenge

Use the datasets called population_UK and deaths_UK to compute yearly mortality rates for:

- all individuals
- individuals below 15 yrs only

Reshaping data frame

For most data analyses, you need:

- one row = one observation
- one column = one variable

Unfortunatelly, it is often not the way people input data!

Reshaping data frame

For most data analyses, you need:

- one row = one observation
- one column = one variable

Unfortunatelly, it is often not the way people input data!

The tidyverse package tidyr offers solutions:

- gather() turns wide data into long
- spread() turns long data into wide

From wide to long

you have:

```
head(my_df1)
## ID Sex age1 age2 age3 age4
## 1 1 girl 81 156 171 181
dim(my_df1)
## [1] 1 6
```

you want:

```
head(my_df2)
## ID Sex Age Height
## 1 1 girl age1
                   81
## 2 1 girl age2
                   156
## 3 1 girl age3
                   171
## 4 1 girl age4
                   181
dim(my_df2)
## [1] 4 4
```

From wide to long

you have:

```
head(my_df1)
## ID Sex age1 age2 age3 age4
## 1 1 girl 81 156 171 181
dim(my_df1)
## [1] 1 6
```

you want:

```
head(my_df2)
## ID Sex Age Height
## 1 1 girl age1
                   81
## 2 1 girl age2
                  156
## 3 1 girl age3
                  171
## 4 1 girl age4
                   181
dim(my_df2)
## [1] 4 4
```

you do:

```
library(tidyr)
my_df2 <- my_df1 %>%
 gather("Age", "Height", -Sex, -ID) %>%
 arrange(ID, Age)
```

From wide to long

you have:

```
head(my_df1)
## ID Sex age1 age2 age3 age4
## 1 1 girl 81 156 171 181
dim(my_df1)
## [1] 1 6
```

you want:

```
head(my_df2)
## ID Sex Age Height
## 1 1 girl age1
                   81
## 2 1 girl age2
                  156
## 3 1 girl age3
                  171
## 4 1 girl age4
                   181
dim(my_df2)
## [1] 4 4
```

you do:

```
library(tidyr)
my_df2 <- my_df1 %>%
 gather("Age", "Height", -Sex, -ID) %>%
 arrange(ID, Age)
                                or:
my_df2 <- my_df1 %>%
  gather("Age", "Height", 3:ncol(my_df1)) %>%
  arrange(ID, Age)
```

From long to wide

you have:

```
head(my_df2)
## ID Sex Age Height
## 1 1 girl age1
                   81
## 2 1 girl age2
                 156
## 3 1 girl age3 171
## 4 1 girl age4
                  181
dim(my_df2)
## [1] 4 4
```

you want:

```
head(my_df1)
## ID Sex age1 age2 age3 age4
## 1 1 girl 81 156 171 181
dim(my_df1)
## [1] 1 6
```

From long to wide

you have:

```
head(my_df2)
## ID Sex Age Height
## 1 1 girl age1
## 2 1 girl age2 156
## 3 1 girl age3 171
## 4 1 girl age4
                   181
dim(my_df2)
## [1] 4 4
```

you want:

```
head(my_df1)
## ID Sex age1 age2 age3 age4
## 1 1 girl 81 156 171 181
dim(my_df1)
## [1] 1 6
```

you do:

```
my_df2 %>%
 spread(-Sex, -ID)
## ID Sex age1 age2 age3 age4
## 1 1 girl 81 156 171 181
```

Note: but why on Earth would you need that?!

Some other useful functions from tidyr

unite() merges 2 columns of a data frame:

```
my_df3 <- my_df2 %>% unite(New_col, ID, Sex)
head(my_df3)
    New_col Age Height
## 1 1_girl age1
## 2 1_girl age2
                   156
## 3 1_girl age3
                   171
## 4 1_girl age4
                   181
```

Some other useful functions from tidyr

unite() merges 2 columns of a data frame:

```
my_df3 <- my_df2 %>% unite(New_col, ID, Sex)
head(my_df3)
    New_col Age Height
## 1 1_girl age1
## 2 1_girl age2
                   156
## 3 1_girl age3
                  171
## 4 1_girl age4
                  181
```

separate() splits 2 columns of a data frame:

```
my_df3 %>% separate(New_col, c("ID", "Sex"))
    ID Sex Age Height
## 1 1 girl age1
## 2 1 girl age2
                  156
## 3 1 girl age3
                  171
## 4 1 girl age4
                  181
```

Some other useful functions from tidyr

unite() merges 2 columns of a data frame:

```
my_df3 <- my_df2 %>% unite(New_col, ID, Sex)
head(my_df3)

## New_col Age Height
## 1 1_girl age1 81
## 2 1_girl age2 156
## 3 1_girl age3 171
## 4 1_girl age4 181
```

separate() splits 2 columns of a data frame:

```
my_df3 %% separate(New_col, c("ID", "Sex"))
## ID Sex Age Height
## 1 1 girl age1 81
## 2 1 girl age2 156
## 3 1 girl age3 171
## 4 1 girl age4 181
```

Note: the R base equivalent are paste() and strsplit() but they are a bit more tedious to use.

Getting started with R

- Introduction

What are tibbles?

Tibbles are modified data frames that are automatically created by tidyverse packages:

```
iris_tbl <- iris %>%
  group by (Species) %>%
 mutate(Sepal.Length.meam = mean(Sepal.Length))
iris_tbl
## # A tibble: 150 x 6
## # Groups:
               Species [3]
      Sepal.Length Sepal.Width Petal.Length Petal.Width Species Sepal.Length.meam
             <dbl>
                          <dbl>
                                                   <dbl> <fct>
##
                                       <dbl>
                                                                              <dbl>
               5.1
                           3.5
                                                     0.2 setosa
##
                                         1.4
                                                                               5.01
               4.9
                                         1.4
                                                     0.2 setosa
                                                                               5.01

                                                                               5.01
               4.6
                           3.4
                                        1.4
                                                     0.3 setosa
                                                                               5.01
                           3.4
                                         1.5
                                                     0.2 setosa
                                                                               5.01
                            2.9
                                         1.4
                                                                               5.01
                                                     0.2 setosa
## 10
               4.9
                            3.1
                                         1.5
                                                     0.1 setosa
                                                                               5.01
## # ... with 140 more rows
```

Note: most of what works on objects of class data.frame works on objects of class tbl (but not all as they don't consider row names).

From tibbles to data frames and back

You can easily convert one into the other:

```
head(as.data.frame(iris_tbl))
    Sepal.Length Sepal.Width Petal.Length Petal.Width Species Sepal.Length.meam
             5.1
                        3.5
                                    1.4
                                               0.2 setosa
                                                                      5.006
## 2
             4.9
                        3.0
                                    1.4
                                               0.2 setosa
                                                                      5.006
## 3
             4.7
                        3.2
                                    1.3
                                               0.2 setosa
                                                                      5.006
             4.6
                       3.1
                                    1.5
                                               0.2 setosa
                                                                      5.006

## # ... with 140 more rows
```

From tibbles to data frames and back

You can easily convert one into the other:

```
head(as.data.frame(iris_tbl))
    Sepal.Length Sepal.Width Petal.Length Petal.Width Species Sepal.Length.meam
                         3.5
                                                  0.2 setosa
             5.1
                                      1.4
                                                                         5.006
## 2
             4.9
                         3.0
                                      1.4
                                                  0.2 setosa
                                                                         5.006
## 3
             4.7
                         3.2

                                                                               5.01
## # ... with 140 more rows
```

Note: for linear models, it is safer to convert everything into data frames!

79 / 87

How to influence the display of tibbles?

You can change the number of rows being displayed:

```
print(iris_tbl, n = 2)
## # A tibble: 150 x 6
## # Groups: Species [3]
    Sepal.Length Sepal.Width Petal.Length Petal.Width Species Sepal.Length.meam
           <dbl>
                       <dbl>
                                    <dbl>
                                                <dbl> <fct>
                                                                          <dbl>
## 1
             5.1

## 8
## # ... with 142 more rows
```

Note: to always display all row you can set options(dplyr.print_min = Inf).

How to influence the display of tibbles?

You can change the number of digits being displayed:

Default:

```
x <- as_tibble(data.frame(pi = pi))
x
## # A tibble: 1 x 1
## pi
## <dbl>
## 1 3.14
```

How to influence the display of tibbles?

You can change the number of digits being displayed:

Default:

Changing setting:

```
old_opt <- options(pillar.sigfig = 10)
x
## # # A tibble: 1 x 1
## pi
## <dbl>
## 1 3.141592654
```

How to influence the display of tibbles?

You can change the number of digits being displayed:

Default:

```
x <- as_tibble(data.frame(pi = pi))
x
## # A tibble: 1 x 1
## pi
## <dbl>
## 1 3.14
```

Changing setting:

```
old_opt <- options(pillar.sigfig = 10)
x
## # A tibble: 1 x 1
## pi
## <dbl>
## 1 3.141592654
```

Reseting setting:

```
options(old_opt)
x
## # A tibble: 1 x 1
## pi
## <dbl>
## 1 3.14
```

tibbles

How to influence the display of tibbles?

Sometimes the default is a little too dangerous!

foo <- c(178, 175, 159, 164, 183, 160, 181, 189, 174, 177)

```
level <- c(rep("A", 6), rep("B", 4))</pre>
d <- data.frame(foo, level)</pre>
d %>%
     group_by(level) %>%
     summarize(Mean = mean(foo))
## # A tibble: 2 x 2
     level Mean
     <fct> <dbl>
            170.
```

2 B

180.

tibbles

How to influence the display of tibbles?

Sometimes the default is a little too dangerous!

```
foo <- c(178, 175, 159, 164, 183, 160, 181, 189, 174, 177)
level <- c(rep("A", 6), rep("B", 4))</pre>
d <- data.frame(foo, level)</pre>
d %>%
     group_by(level) %>%
     summarize(Mean = mean(foo))
## # A tibble: 2 x 2
     level Mean
     <fct> <dbl>
            170.
## 2 B
            180.
```

Compare to base R:

```
c(mean(foo[level == "A"]), mean(foo[level == "B"]))
## [1] 169.8333 180.2500
```

Note: but at least they have recently added the "." suggesting there are more number out there!

Getting started with \boldsymbol{R}

- Introduction
- Vectors
- Matrices and arrays
- 4 List
- Data frames and tibbles
- 6 Importing & exporting data

Working directory

Before anything, you must know where you read & write on your hard drive!

```
getwd() ## get the working directory, to change it use setwd()
## [1] "/Users/alex/Dropbox/Boulot/Mes_projets_de_recherche/R_packages/BeginR_project/BeginR/sources_vignettes/usingdata"
dir() ## list all files in the working directory
## [1] "usingdata.nav" "usingdata.pdf" "usingdata.pdf.asis" "usingdata.Rnw" "usingdata.snm"
## [6] "usingdata.tex" "usingdata.toc" "usingdata.vrb"
dir(pattern = "*.csv") ## list all ffiles with the extension csv
## character(0)
```

Note: you can also set this up with RStudio but it won't be saved unless you set up a project file.

Exporting and importing data in the ${\bf R}$ binary format

 ${f R}$ can write and read binary formats that take by convention the extensions .rda or .RData.

Example:

```
my_iris <- iris
save(my_iris, file = "my_iris.rda") ## check the help for compression</pre>
```

Exporting and importing data in the R binary format

 ${f R}$ can write and read binary formats that take by convention the extensions .rda or .RData.

Example:

```
my_iris <- iris
save(my_iris, file = "my_iris.rda") ## check the help for compression

rm(list = ls()) ## removes everything!
head(my_iris)
## Error in head(my_iris): object 'my_iris' not found</pre>
```

Exporting and importing data in the R binary format

Sepal.Length Sepal.Width Petal.Length Petal.Width Species

1.4

1.3

1.5

1.4

1.7

3.5

3.0

3.2

3.1

3.6

3.9

 ${\sf R}$ can write and read binary formats that take by convention the extensions .rda or .RData.

0.2 setosa

0.2 setosa

0.2 setosa

0.2 setosa

0.2 setosa

0.4 setosa

Example:

1

2

3

4

5

6

my_iris <- iris

```
save(my_iris, file = "my_iris.rda") ## check the help for compression

rm(list = ls()) ## removes everything!
head(my_iris)

## Error in head(my_iris): object 'my_iris' not found

load(file = "my_iris.rda")
head(my_iris)
```

Note: this is useful and best for **R** to **R** exchanges (but it is useless without **R**).

4.7

4.6

5.0

5.4

Exporting and importing data sets in plain text

- R cannot read/write .xls(x) files out of the box
- Several packages can do that, but it is safer to use .csv or .txt files
- Excel can read and write .csv & .txt files!

Writing a data set:

```
write.csv(my_iris, file = "my_iris.csv", row.names = FALSE)
```

Exporting and importing data sets in plain text

- R cannot read/write .xls(x) files out of the box
- Several packages can do that, but it is safer to use .csv or .txt files
- Excel can read and write .csv & .txt files!

Writing a data set:

```
write.csv(my_iris, file = "my_iris.csv", row.names = FALSE)
```

Reading a data set:

```
rm(my_iris) ## delete the object my iris
my iris <- read.csv("my iris.csv") ## or read.table() with adequate options!
head(my_iris)
    Sepal.Length Sepal.Width Petal.Length Petal.Width Species

Exporting and importing data sets in plain text

- R cannot read/write .xls(x) files out of the box
- Several packages can do that, but it is safer to use .csv or .txt files
- Excel can read and write .csv & .txt files!

Writing a data set:

```
write.csv(my_iris, file = "my_iris.csv", row.names = FALSE)
```

Reading a data set:

```
rm(my_iris) ## delete the object my iris
my iris <- read.csv("my iris.csv") ## or read.table() with adequate options!
head(my_iris)
    Sepal.Length Sepal.Width Petal.Length Petal.Width Species
## 1
              5.1
                          3.5
                                       1.4
                                                   0.2 setosa
## 2
             4.9
                          3.0
                                       1.4
                                                   0.2 setosa
             4.7
                         3.2
                                      1.3
                                                  0.2 setosa
             4.6
                         3.1
                                      1.5
                                                   0.2 setosa
              5.0
                         3.6
                                       1.4
                                                   0.2 setosa
## 5
             5.4
                                      1.7
## 6
                          3.9
                                                   0.4 setosa
```

- Note 1: always check your file in a text editor before importing it or use RStudio "File/Import Datasets GUI".
- Note 2: you will have often to change the arguments sep (and dec if you are german).
- Note 3: setting stringsAsFactors = FALSE can avoid a lot of troubles!

Challenge

Create a data frame using your favorite spreadsheet software (or choose an existing one) and import it in \mathbf{R} .
